Cystic lesion of the fourth ventricle
Role of CISS

A 13-year-old boy presented with headache of 1 month and vomiting for 10 days. Salient examination findings were left lateral rectus paresis and papilledema. A contrast-enhanced CT followed by MRI brain revealed an ill-defined fourth ventricular cyst with communicating hydrocephalus (figure 1). Subsequently, a constructive interference in steady state (CISS) sequence revealed a fourth ventricular cysticercus (figure 2).

Intraventricular neurocysticercus may be missed on conventional CT and MRI.1 A distinctly visible scolex and CISS sequence, with its higher contrast-to-noise ratio and accentuation of T2 value between the cyst and CSF, rules out malignant radiologic differentials.2

Lokesh Saini, MD, Biswaroop Chakrabarty, DM, Atin Kumar, MD, Sheffali Gulati, MD
From the All India Institute of Medical Sciences, New Delhi, India.

Author contributions: Dr. Saini and Dr. Chakrabarty worked up the patient and prepared the manuscript under the guidance of Dr. Gulati. Dr. Kumar provided the radiologic inputs.

Study funding: No targeted funding reported.

Disclosure: The authors report no disclosures relevant to the manuscript. Go to Neurology.org for full disclosures.
